C++ Socket Server & POSIX Wrapper

A lightweight, object-oriented C++ TCP Socket Server wrapper designed for POSIX/Linux systems. This library encapsulates low-level socket system calls (`socket` , `bind` , `listen` , `accept` , `read` , `write`) into an easy-to-use Class architecture.

Developer Profile

Features

- **Object-Oriented Design:** Clean `my::sock` namespace and C++ class encapsulation.
- **POSIX Socket Integration:** Native wrapper for system socket calls.
- **Address Reuse:** Includes `SO_REUSEADDR` flag in `bind_socket()` to prevent port binding locks.
- **System Command Execution:** Integrates received commands directly with system-level execution using `std::system()` .
- **Automatic Cleanup:** Destructor handles socket closure (`close(df)`) to prevent file descriptor leaks.

Project Structure

```
.
    sock.hpp     # Socket class definition and interface header
    sock.cpp     # Socket methods implementation
```

```
main.cpp     # Application entry point (Server loop & execution)
Makefile     # Build automation script
```
